Beijing Computational Science Research Center (CSRC) Spring School on the lattice Boltzmann method, May 2-6, 2011

Collaborations: Prof. Taku Ohwada, Prof. Ilya Karlin
Outline of this talk

1. Advection process
   - Some relevant scalings
   - Asymptotic analysis
   - Bad news and good news

2. Relaxation process
   - Local equilibrium (EQ)
   - Generalized Local Equilibrium (GE)
   - Examples of local quasi-equilibrium (QE)

3. Kinetic models
   - Killing acoustic modes
   - Killing checkerboard modes
   - Implementation and coding
   - Generalization: the quasi-equilibrium chain
What is the Lattice Boltzmann Method?

“The lattice Boltzmann method (LBM) is used for the numerical simulation of physical phenomena and serves as an alternative to classical solvers of partial differential equations (PDEs)” [www.lbmethod.org/]. The main unknown is the discrete distribution function, from which all relevant macroscopic quantities (satisfying some target PDEs) can be derived.

The operative formula consists of the (a) advection process and (b) the relaxation process

\[ f(\hat{x} + v, \hat{t} + 1) - f(\hat{x}, \hat{t}) = -\omega \left[ f(\hat{x}, \hat{t}) - f_{EQ}(\hat{x}, \hat{t}) \right], \quad (1) \]

while the computer implementation consists of the streaming and the collision step, defined as follows:

\[ f(\hat{x} + v, \hat{t} + 1) = f^*(\hat{x}, \hat{t} + 1), \quad (2) \]

\[ f^*(\hat{x}, \hat{t} + 1) = f(\hat{x}, \hat{t}) - \omega \left[ f(\hat{x}, \hat{t}) - f_{EQ}(\hat{x}, \hat{t}) \right]. \quad (3) \]
Diligent student :

- The **advection process** requires to understand the concept of **scaling** for properly interpreting the numerical results: in particular, the Boltzmann scaling, which is useful for coding, and the diffusive scaling, which is useful for dealing with low Mach number flows.
- The **relaxation process** can be generalized by the concept of **quasi-equilibrium (QE)**, i.e. an intermediate state ruling the dynamics of the discrete distribution function towards the equilibrium (EQ), leading to the Generalized Local Equilibrium (GE=QE+EQ).

Lazy student :

- Both previous concepts are difficult! Can we avoid them?
- As far as the incompressible regime of the continuum description (based on Navier-Stokes equations) is concerned, an alternative is provided by the (revisited) Artificial Compressibility Method (ACM). Stay tuned on the lecture by Professor Ohwada later today!

   - Generalization: the quasi-equilibrium chain
The advection process requires to understand the concept of scaling for properly interpreting the numerical results: in particular, the Boltzmann scaling, which is useful for coding, and the diffusive scaling, which is useful for dealing with low Mach number flows.

For sake of simplicity, let us consider the following approximation (it will be removed soon, when introducing the lattice)

\[ f(\hat{x} + \mathbf{v}, \hat{t} + 1) - f(\hat{x}, \hat{t}) \approx \frac{\partial f}{\partial \hat{t}} + \mathbf{v} \cdot \frac{\partial f}{\partial \hat{x}}. \]  

In this notes, we will not discuss the Method of Characteristics (MOC), even though this is fundamental for understanding the on-lattice dynamics of the discrete distribution function.
Basics of Kinetic Theory

- The **Boltzmann equation** is the basic equation in kinetic theory of gases and describes the time evolution of the distribution function of gas molecules, which is the function of time, space coordinate, and molecular velocity.

- **Bhatnagar-Gross-Krook (BGK) model equation** inherits the main features of the full Boltzmann equation and the fluid-dynamic description solution of BGK solution for small Knudsen numbers is obtained in a much simpler way. It is quite natural and advantageous to employ the BGK equation as the basis of kinetic method for incompressible Navier-Stokes.

- In particular we will employ the simplified BGK equation, i.e. the isothermal distribution, and the collision frequency independent of the local state.
Bhatnagar-Gross-Krook (BGK) Model Equation

BGK for single-particle distribution function \( f(x, v, t) \):

\[
\frac{\partial f}{\partial \hat{t}} + v \cdot \frac{\partial f}{\partial \hat{x}} = \omega(\rho)(f_{tEQ} - f),
\]

(5)

where \( \hat{x}_i, \hat{t}, \) and \( v_i \) are the dimensionless space coordinates, time, and molecular velocity components respectively; \( \omega(\rho) \) is the relaxation frequency (strictly positive function) and \( f_{tEQ}(\rho, u, e, v, t) \) is the equilibrium distribution function defined as

\[
f_{tEQ} = \frac{\rho/m}{(2\pi e)^{d/2}} \exp \left[ -\frac{(v - u)^2}{2e} \right],
\]

(6)

where the moments \( \rho, u \) and \( e \) can be expressed by means of the operator \( \langle\langle \cdot \rangle\rangle = \int \cdot \Pi_{i=1}^{d} dv_i \) as

\[
\rho = m\langle\langle f \rangle\rangle, \quad \rho u = m\langle\langle v f \rangle\rangle, \quad \rho e = m\langle\langle \frac{1}{2}(v - u)^2 f \rangle\rangle.
\]
In the incompressible continuum limit, the Mach number as well as the Knudsen number is vanishingly small and the deviations of temperature and density are vanishingly small. Then, we can employ the simplified BGK equation, i.e.

- the isothermal equilibrium distribution $f_{t\text{EQ}} \to f_{\text{EQ}}$, namely

$$f_{\text{EQ}} = \frac{\rho}{2 \pi/3} \exp \left[ - \frac{3(v_i - u_i)^2}{2} \right], \quad (7)$$

where $m = 1$ (since it is a constant), $d = 2$ (for two dimensional case) and $e = 1/3$ are assumed;

- and the collision frequency independent of the local state, namely $\omega(\rho) \to \omega$. 

Advection process

Boltzmann Scaling

- Let us define $c$ the particle speed, i.e. the average modulus of the particle velocity (of the order of the sound speed).

- In the previous simplified BGK equation, the so-called Boltzmann scaling was used, i.e. the unit of space coordinate and that of time variable were the mean free path $l_c (= c T_c)$ and the mean collision time $T_c$, respectively → in this way $|v| = O(1)$ and $\omega = O(1)$.

- Obviously, they are not appropriate as the characteristic scales for flow field in the continuum limit. Let the characteristic length scale of the flow field be $L$ and let the characteristic flow speed be $U$. There are two factors in the incompressible continuum limit:
  - the continuum limit means $l_c \ll L$;
  - and the incompressible limit means $U \ll c$. 
Diffusive Scaling

In the following asymptotic analysis, we introduce the other dimensionless variables, defined by

$$x_i = \left(\frac{l_c}{L}\right) \hat{x}_i, \quad t = \left(\frac{UT_c}{L}\right) \hat{t}. \quad (8)$$

Defining the small parameter $\epsilon$ as $\epsilon = \frac{l_c}{L}$, which corresponds to the Knudsen number, we have $x_i = \epsilon \hat{x}_i$. Furthermore, assuming

$$U/c = \epsilon, \quad (9)$$

which is the key of derivation of the incompressible limit (Sone), we have $t = \epsilon^2 \hat{t}$. Then, BGK equation is rewritten as

$$\epsilon^2 \frac{\partial f}{\partial t} + \epsilon v_i \frac{\partial f}{\partial x_i} = \omega \left( f_{EQ} - f \right). \quad (10)$$

In this new scaling, we can assume $\partial_\alpha f = \partial f / \partial \alpha = O(f)$ and $\partial_\alpha M = \partial M / \partial \alpha = O(M)$, where $\alpha = t, x_i$ and $M = \rho, u_i$. 

Pietro Asinari, PhD (Politecnico di Torino)
Clearly the solution of the BGK equation depends on $\epsilon$. The solution for small $\epsilon$ is investigated in the form of the asymptotic regular expansion

$$f = f^{(0)} + \epsilon f^{(1)} + \epsilon^2 f^{(2)} + \cdots.$$  

(11)

$\rho$ and $u_i$ are also expanded:

$$\rho = 1 + \epsilon \rho^{(1)} + \epsilon^2 \rho^{(2)} + \cdots,$$  

(12)

$$u_i = \epsilon u_i^{(1)} + \epsilon^2 u_i^{(2)} + \cdots,$$  

(13)

since the Mach number is $O(\epsilon)$, the perturbations of $u_i$ starts from the order of $\epsilon$. Consequently

$$q_i = \rho u_i = \epsilon q_i^{(1)} + \epsilon^2 q_i^{(2)} + \cdots = \epsilon u_i^{(1)} + \epsilon^2 [u_i^{(2)} + \rho^{(1)} u_i^{(1)}] + \cdots.$$

Regular expansion means $\partial_\alpha f^{(k)} = O(1)$ and $\partial_\alpha M^{(k)} = O(1)$. 

Pietro Asinari, PhD (Politecnico di Torino)
Introducing the previous expansions in $f_{EQ}$ and applying Taylor expansion yields:

$$f_{EQ} = f_{EQ}^{(0)} + \epsilon f_{EQ}^{(1)} + \epsilon^2 f_{EQ}^{(2)} + \cdots,$$

where $f_{EQ}^{(k)}$ ($k = 1, 2, \cdots$) are known polynomial functions of the hydrodynamic moments. Substituting the above expansions into BGK equation and equating the terms of the same order of power of $\epsilon$, we have

$$0 = \omega (f_{EQ}^{(1)} - f^{(1)}),$$

$$\frac{\partial f^{(k-2)}}{\partial t} + v_i \frac{\partial f^{(k-1)}}{\partial x_i} = \omega (f_{EQ}^{(k)} - f^{(k)}) \quad (k \geq 2).$$

The above equations give the functional forms of $f^{(k)}$ as the functions of lower moments.
Orthogonality Conditions

Since $\rho = \langle\langle f \rangle\rangle = \langle\langle f_{EQ} \rangle\rangle$ and $\rho u = \langle\langle vf \rangle\rangle = \langle\langle vf_{EQ} \rangle\rangle$, then

$\langle\langle f_{EQ} - f \rangle\rangle = \langle\langle v_i (f_{EQ} - f) \rangle\rangle = 0$. Consequently the left hand sides of the previous equations must satisfy the orthogonality conditions

$$\langle\langle \phi \left( \frac{\partial f^{(k-2)}}{\partial t} + v_i \frac{\partial f^{(k-1)}}{\partial x_i} \right) \rangle\rangle = 0 \quad (k \geq 2), \quad (17)$$

where $\phi = 1, v_j$.

- From the above orthogonality conditions, we have the PDE systems for $\rho^{(k)}$ and $u_i^{(k)}$.

- Once these PDE systems are solved under appropriate boundary condition and initial data, the asymptotic solution for the simplified BGK equation is determined.
Incompressible Navier-Stokes System for $u^{(1)}$ and $p^{(2)}$

The equations for the leading coefficients $u^{(1)}$ and $p^{(2)}$ are given by the incompressible Navier-Stokes (ICNS) system of equations, namely

\begin{align}
\nabla \cdot u^{(1)} &= 0, \\
\partial_t u^{(1)} + \nabla u^{(1)} \cdot u^{(1)} + \nabla p^{(2)} &= \nu \nabla^2 u^{(1)},
\end{align}

where the kinematic viscosity is $\nu = \tau / 3$ and $\tau = 1 / \omega$, i.e. the relaxation time. This means that, in addition to what we want to solve, some additional terms exist, which are due to higher-order kinetic effects. It is possible to combine the previous equations in the Poisson equation, namely

\begin{align}
\nabla \cdot [\nabla u^{(1)} u^{(1)}] + \nabla^2 p^{(2)} &= 0.
\end{align}
Homogeneous Oseen system for $u^{(2)}$ and $p^{(3)}$

The next PDE system for coefficients $u^{(2)}$ and $p^{(3)}$ is given by the homogeneous (linear) Oseen system, namely

\begin{align}
\nabla \cdot u^{(2)} &= 0, \\
\partial_t u^{(2)} + \nabla u^{(2)} u^{(1)} + \nabla u^{(1)} u^{(2)} + \nabla p^{(3)} &= \nu \nabla^2 u^{(2)}.
\end{align}

Clearly, if proper initial data and boundary conditions are considered, the previous system of equations admits the null solution and its dynamics is irrelevant for the considered simplified model, namely $u^{(2)} = 0$ and $p^{(3)} = 0 \rightarrow$ This result is general in the sense that an odd/even decomposition exists for the hydrodynamic moments, i.e. only odd terms appear in the expansion of $u$ and even terms in that of $p$ (Junk).
Finally the Burnett-like system is recovered

$$\partial_t \rho^{(2)} + \nabla \cdot q^{(3)} = 0,$$

(23)

$$\partial_t q^{(3)} + \nabla \cdot [u^{(1)} \otimes q^{(3)}] + \nabla \cdot [q^{(3)} \otimes u^{(1)}] + \nabla p^{(4)} =$$

$$\nu \nabla^2 q^{(3)} + \nu \nabla \nabla \cdot q^{(3)} + i_3,$$

(24)

where $i_3$ is a forcing term [1], defined as

$$i_3 = \tau \nabla \left[ \nu \nabla^2 u^{(1)} - \nabla u^{(1)} u^{(1)} - \nabla p^{(2)} \right] u^{(1)}$$

$$+ \tau \nabla u^{(1)} \left[ \nu \nabla^2 u^{(1)} - \nabla u^{(1)} u^{(1)} - \nabla p^{(2)} \right]$$

$$+ \tau \nabla \cdot \nabla \cdot \left[ u^{(1)} \otimes u^{(1)} \otimes u^{(1)} \right] + \tau^2 \nabla^2 \nabla p^{(2)}$$

$$- \tau^2 / 3 \nabla^2 \left[ \nabla u^{(1)} u^{(1)} \right] + \tau^3 / 9 \nabla^2 \nabla^2 u^{(1)}.$$

(25)
Since in general the forcing term $i_3$ is not null, then the kinetic-like effects are of the order of $Kn^2$, namely

$$\frac{u - \epsilon u^{(1)}}{\epsilon} \sim O(\epsilon^2), \quad \frac{p - [1 + \epsilon^2 p^{(2)}]}{\epsilon^2} \sim O(\epsilon^2). \quad (26)$$

The previous effects must be defined kinetic-like and not truly kinetic, because the original simplified kinetic model cannot be considered completely reliable up to any order, because of the original simplifications (isothermal flow and relaxation frequency independent of the local conditions).

For this reason, the higher-order terms should be regarded as an error due to the adopted simplified model.
The Lattice, i.e. the finite set of discrete velocities

- Let us assume that $v$ belongs to a finite set of discrete velocities $\{v_\alpha\}$, i.e. a lattice (for distinguishing it from the spatial mesh), namely
  \[ v_\alpha \in \{v\}, \quad (27) \]
  \[ f_\alpha(\hat{x}, \hat{t}) = f(\hat{x}, v_\alpha, \hat{t}) \in \{f\}. \quad (28) \]

- Clearly, the lattice is usually selected such that if $\hat{x}$ is a point of the spatial mesh than also $\hat{x} + v_\alpha$ belongs to the same mesh.

- Let us denote $\langle \cdot \rangle$ a sum over the discrete velocity index (in the following, this symbol alone means that the argument is a proper vector defined on the considered lattice without further specifications, namely $\langle \{f\} \rangle = \langle f \rangle$).

- Let $f$ and $g$ be the lists defined by $f = [f_0, f_1, f_2, \cdots, f_{Q-1}]^T$ and $g = [g_0, g_1, g_2, \cdots, g_{Q-1}]^T$. Then, $fg$ is the list defined by $[f_0g_0, f_1g_1, f_2g_2, \cdots, f_{Q-1}g_{Q-1}]^T$. 

Pietro Asinari, PhD (Politecnico di Torino)
Let us consider the **D2Q9 lattice**: $v_0 = (0, 0)$, $v_\alpha = (\pm c, 0)$ and $(0, \pm c)$ for $\alpha = 1–4$, and $v_\alpha = (\pm c, \pm c)$ for $\alpha = 5–8$, where $c$ is the lattice spacing.

The D2Q9 lattice derives from the **three–point Gauss–Hermite formula**, with the following weights $w(-1) = 1/6$, $w(0) = 2/3$ and $w(+1) = 1/6$.

Let us arrange in the list $v_x$ ($v_y$) all the components of the lattice velocities along the $x$–axis ($y$–axis) and in the list $f$ all the populations $f_\alpha$. Algebraic operations for the lists are always assumed **component-wise**.

The sum of all the elements of the list $p$ is denoted by $\langle p \rangle = \sum_{\alpha=0}^{Q-1} p_\alpha$. The dimensionless density $\rho$, the flow velocity $u$ and the pressure tensor $\Pi$ are defined by $\rho = \langle f \rangle$, $\rho u_i = \langle v_i f \rangle$ and $\rho \Pi_{ij} = \langle v_i v_j f \rangle$ respectively.
The ratio $h$ between the grid spacing and the characteristic length of the flow can be expressed as $h = \epsilon \delta \hat{x} = \epsilon$, i.e. the dimensionless grid spacing is equal to the Knudsen number $\rightarrow$

This proves that the Knudsen number for the present scheme does not have a pure physical meaning.

The nodal values in the numerical scheme can be expressed by means of a Taylor expansion, recalling that $\hat{t} = t/\epsilon^2$ and $\hat{x} = x/\epsilon$, namely

$$\{f\}(x, t + \epsilon^2) = \sum_{k=0}^{\infty} \frac{\epsilon^{2k}}{k!} (\partial/\partial t)^k \{f\}(x, t), \quad (29)$$

$$\{f\}(x + \epsilon \{v\}, t) = \sum_{k=0}^{\infty} \frac{\epsilon^k}{k!} (\partial_S)^k \{f\}(x, t), \quad (30)$$

where $\partial_S = \{v\} \cdot \nabla$ (while $\partial_s = v \cdot \nabla$ in the continuous case).
Since the grid spacing is expressed in terms of the Knudsen number, it is possible for the LBM scheme to repeat the asymptotic analysis taking into account the discrete effects. First of all, the expansion coefficients \( f^{(k)} \) change, namely

\[
\begin{align*}
\{ f^{(1)} \} &= \{ f_{EQ}^{(1)} \}, & \{ f^{(2)} \} &= \{ f_{EQ}^{(2)} \} - \tau \partial_S \{ f_{EQ}^{(1)} \}, \\
\{ f^{(3)} \} &= \{ f_{EQ}^{(3)} \} - \tau \left( \partial_t \{ f_{EQ}^{(1)} \} + \partial_S \{ f_{EQ}^{(2)} \} - \tilde{\tau}_1 \partial_S^2 \{ f_{EQ}^{(1)} \} \right),
\end{align*}
\]

where \( \tilde{\tau}_1 = \tau - 1/2 \), instead of

\[
\begin{align*}
f^{(1)} &= f_{EQ}^{(1)}, & f^{(2)} &= f_{EQ}^{(2)} - \tau \partial_S f_{EQ}^{(1)}, \\
f^{(3)} &= f_{EQ}^{(3)} - \tau \left[ \partial_t f_{EQ}^{(1)} + \partial_S f_{EQ}^{(2)} - \tau \partial_S^2 f_{EQ}^{(1)} \right].
\end{align*}
\]
Discrete Effects in the High-Order Moments

The few discrete velocities and consequently the truncated local equilibrium show their limits in the high-order moments, because of:

- the lack of some terms, which are tensors of the macroscopic velocity with order higher than the second;

\[
\langle \{v\} \cdot \partial^2_S \{f_{EQ}^{(3)}\} \rangle = \frac{1}{3} \nabla^2 q^{(3)} + \frac{2}{3} \nabla \nabla \cdot q^{(3)},
\]

\[
\langle \langle v \partial^2_s f_{EQ}^{(3)} \rangle \rangle = \frac{1}{3} \nabla^2 q^{(3)} + \frac{2}{3} \nabla \nabla \cdot q^{(3)} + \nabla \cdot \nabla \cdot [u^{(1)} \otimes u^{(1)} \otimes u^{(1)}],
\]

- the inadequate symmetry properties producing terms, which cannot be expressed in tensorial form.

\[
\langle \{v\} \cdot \partial^3_S \{f_{EQ}^{(2)}\} \rangle = \nabla \cdot \nabla \nabla \cdot u^{(1)} \otimes u^{(1)} - D(D\nabla)^3 u^{(1)} \otimes u^{(1)},
\]

\[
\langle \langle v \partial^3_s f_{EQ}^{(2)} \rangle \rangle = \nabla \cdot \nabla \nabla \cdot u^{(1)} \otimes u^{(1)}.\]
The leading error term consists of four factors which degrade the real Burnett to Burnett-like phenomena, namely

1. the isothermal flow condition imposed at kinetic level (continuous too);
2. the relaxation frequency assumed independent of the local conditions (continuous too);
3. the dissatisfaction of the rotation symmetry for higher order moments due to the velocity discretization;
4. the assumed truncated definition of the local equilibrium.
Let us multiply Eq. (23) by $\epsilon^2$ and let us sum to it Eq. (18), namely
\[ \epsilon^2 \partial_t \rho^{(2)} + \nabla \cdot (u^{(1)} + \epsilon^2 q^{(3)}) = 0. \quad (35) \]

Taking into account that $\rho^{(2)} = 3p^{(2)}$, defining $u' = u^{(1)} + \epsilon^2 q^{(3)}$ and $p' = p^{(2)}$ yield
\[ 3\epsilon^2 \partial_t p' + \nabla \cdot u' = 0, \quad (36) \]
and consequently Eq. (19) becomes
\[ \partial_t u' + \nabla u' u' + \nabla p' = \nu \nabla^2 u' + O(\epsilon^2). \quad (37) \]

Neglecting the last term in the previous equation leads to the Artificial Compressibility Method (ACM), which is also second order accurate in solving the incompressible Navier-Stokes equations. This method is a re-visitation of Chorin’s method for steady solutions because ACM works also for transient solutions, since the term $\epsilon^2$ is proportional to the discrete time step [2].
Outline Compass

1. Advection process
   - Some relevant scalings
   - Asymptotic analysis
   - Bad news and good news

2. Relaxation process
   - Local equilibrium (EQ)
   - Generalized Local Equilibrium (GE)
   - Examples of local quasi-equilibrium (QE)

3. Kinetic models
   - Killing acoustic modes
   - Killing checkerboard modes
   - Implementation and coding
   - Generalization: the quasi-equilibrium chain
In this section, we discuss the relaxation process.

The relaxation process can be generalized by the concept of quasi-equilibrium (QE), i.e. an intermediate state ruling the dynamics of the discrete distribution function towards the equilibrium (EQ), leading to the Generalized Local Equilibrium (GE=QE+EQ).

The relaxation process is described by the collisional operator, namely

\[
J = -\omega \left[ f(\hat{x}, \hat{t}) - f_{EQ}(\hat{x}, \hat{t}) \right],
\]

(38)

which drives the discrete distribution function towards the local equilibrium.

The local equilibrium is a function of the conserved moments, namely \( \rho = \langle f \rangle = \langle f_{EQ} \rangle \) and \( \rho u = \langle v f \rangle = \langle v f_{EQ} \rangle \), and it can be derived by means of a constrained optimization problem (the so-called “MaxEnt” problem).
Entropy $S$ is a concave Lyapunov function with non-degenerated Hessian. Any Lyapunov function may be used.

Nevertheless, most of famous entropies, like the relative Boltzmann-Gibbs-Shannon entropy, the Rényi entropy, the Burg entropy, the Cressie-Read and the Tsallis entropies (a) do not depend on kinetic coefficients for Markov chains and (b) satisfy some natural additivity conditions.

The entropy function $S = -H$, where $H$ is the $H$–function, for the D2Q9 lattice is [3]

$$S(f) = -H(f) = -\langle f \ln (f/W) \rangle,$$

where $W = w(v_x)w(v_y)$ and the equilibrium population list is

**Definition of Local Equilibrium ($f_{EQ}$)**

$$f_{EQ} = \min_{f \in P_{EQ}} H(f), \text{ where } P_{EQ} \text{ is the set of functions such that }$$

$$P_{EQ} = \{ f > 0 : \langle f \rangle = \rho, \langle vf \rangle = \rho u \}$$
The method of **Lagrange multipliers** provides a strategy for finding the previous constrained minimum.

**Definition of Lagrange function ($\Lambda_{EQ}$)**

$$
\Lambda_{EQ} = \langle f \ln (f/W) \rangle + \lambda \rho (\langle f \rangle - \rho) + \lambda u \cdot (\langle vf \rangle - \rho u)
$$

In particular, it is easy to prove that the minimization of the Lagrange function leads to

$$
\ln (f_{EQ}) = \ln (\rho A) + \sum_{i=x,y} (v_i/c) \ln (B_i),
$$

or equivalently

$$
f_{EQ} = \rho A \prod_{i=x,y} B_i^{v_i/c}.
$$
Local Equilibrium (Maxwellian state)

- The convex entropy function ($H$–function) for this lattice is [3]
  \[ H(f) = \langle f \ln (f/W) \rangle, \]  
  \[ (42) \]
  where $W = w(v_x) w(v_y)$ and the equilibrium population list is

**Definition of Local Equilibrium ($f_{EQ}$)**

\[ f_{EQ} = \min_{f \in P_{EQ}} H(f), \]  
where $P_{EQ}$ is the set of functions such that

\[ P_{EQ} = \{ f > 0 : \langle f \rangle = \rho, \langle vf \rangle = \rho u \} \]

- Minimization of the $H$–function under the constraints of mass and momentum conservation yields [5]
  \[ f_{EQ} = \rho \prod_{i=x,y} w(v_i) (2 - \varphi(u_i/c)) \left( \frac{2(u_i/c) + \varphi(u_i/c)}{1 - (u_i/c)} \right)^{v_i/c}, \]
  \[ (43) \]
  where $\varphi(z) = \sqrt{3z^2 + 1}$. In order to ensure the positivity of $f_M$, the low Mach number limit must be considered, i.e. $|u_i| < c$. 
The easiest way to relax the discrete distribution function towards the equilibrium is given by the Bhatnagar-Gross-Krook (BGK) model, namely $J = \omega (f_{EQ} - f)$.

However, the basic idea for going beyond BGK is to improve the stability of the LBM schemes with regards to rough meshes, but preserving the required level of accuracy.

In recent years, many approaches have been developed for the previous goal (see the lecture by Professor Luo at the end of the week!):

1. the multiple–relaxation–time (MRT) schemes with tunable bulk viscosity, which is a free parameter to dump the compressibility error, when searching for the incompressible limit [6, 7, 8];
2. the entropic (ELB) schemes, which use equilibria derived by a constrained optimization problem based on the $H$–function.

However almost all previous approaches can be expressed by means of the Generalized Local Equilibrium (GE).
A simple way to go beyond the BGK model, namely \( J = \omega (f_{EQ} - f) \), is to consider a two-parametric family of LB models based on an intermediate quasi-equilibrium (QE) state of relaxation \( f_{QE} \),

\[
J_Q(f) = \omega_s (f_{EQ} - f_{QE}) + \omega_f (f_{QE} - f),
\]

(44)

where \( \omega_s = 1/\tau_s \) is the slow relaxation frequency and \( \omega_f = 1/\tau_f \) is the fast relaxation frequency.

Formally, the above equation can always be recast in the form of a standard BGK, relaxing to a Generalized Local Equilibrium (GE), namely

\[
J_Q(f) = \omega_f (f_{GE} - f),
\]

(45)

where

\[
f_{GE} = \omega_s/\omega_f f_{EQ} + (1 - \omega_s/\omega_f) f_{QE}.
\]

(46)
How do we define the Local Quasi-equilibrium (QE)?

- The local quasi-equilibrium is the key ingredient for deriving the Generalized Equilibrium (GE) and consequently the collisional operator of the model.

In the following, we will discuss three examples:

1. Example (QE-IID), it is a particular case of a more general formula for unidirectional quasi-equilibria in any dimension and it is based on the canonical constrained optimization;

2. Example (QE-IIT), since the previous quasi-equilibrium is a two-dimensional manifold, it is possible to collapse even further the quasi-equilibrium by getting closer to the equilibrium;

3. Example (QE-III), it is a degenerate case involving the third order moments which are not fully representable on the D3Q9 lattice, hence some pruning must be considered starting from the higher order quasi-equilibria.
Example (1) of Local Quasi–equilibrium (called IID)

- Let us introduce a novel quasi–equilibrium [9, 10, 11] population list, by requiring, in addition, that the diagonal components of the pressure tensor $\Pi$ have some prescribed values, namely

**Definition of Local Quasi-equilibrium ($f_{\text{IID QE}}$)**

$$f_{\text{IID QE}} = \min_{f \in P_{\text{QE}}} H(f),$$

where $P_{\text{QE}} \subset P_{\text{Eq}}$ is the set of functions such that

$$P_{\text{QE}} = \left\{ f > 0 : \langle f \rangle = \rho, \langle \mathbf{v} f \rangle = \rho \mathbf{u}, \langle \mathbf{v}_i^2 f \rangle = \rho \Pi_{ii} \right\}.$$

- In other words, minimization of the $H$–function under the constraints of mass and momentum conservation and prescribed diagonal components of the pressure tensor yields

$$f_{\text{IID QE}} = \rho \prod_{i=x,y} w(v_i) \frac{3 (c^2 - \Pi_{ii})}{2 c^2} \left( \sqrt{\frac{\Pi_{ii} + c u_i}{\Pi_{ii} - c u_i}} \right)^{\frac{v_i}{c}} \left( \frac{2 \sqrt{\Pi_{ii}^2 - c^2 u_i^2}}{c^2 - \Pi_{ii}} \right)^{\frac{v_i^2}{c^2}}. \tag{47}$$
The plane of parameters

In order to ensure the positivity of $f_{\text{QE}}^{\text{HD}}$, we use $\Pi = (\Pi_{xx}, \Pi_{yy}) \in \Omega$ for a generic point on the two-dimensional plane $\Omega = \{ \Pi : c |u_x| < \Pi_{xx} < c^2, c |u_y| < \Pi_{yy} < c^2 \}$ [4].
The calculation of the moments can be performed by means of a linear mapping, namely \( m = M f \), where \( M \) is the non–orthogonal transformation matrix, namely

\[
M = \begin{bmatrix}
1, \ v_x, \ v_y, \ v_x^2, \ v_y^2, \ v_xv_y, \ (v_x)^2v_y, \ v_x(v_y)^2, \ (v_x)^2(v_y)^2
\end{bmatrix}^T, \tag{48}
\]

which involves proper combinations of the lattice velocity components.

Applying this linear mapping yields \( m_{\text{IID QE}} = M \cdot f_{\text{IID QE}} \), where

\[
m_{\text{IID QE}} = \rho \begin{bmatrix}
1, \ u_x, \ u_y, \ \Pi_{xx}, \ \Pi_{yy}, \ u_xu_y, \ u_y\Pi_{xx}, \ u_x\Pi_{yy}, \ \Pi_{xx}\Pi_{yy}
\end{bmatrix}^T. \tag{49}
\]

This clearly shows that the quasi–equilibrium moments depend only on the constrained quantities, i.e. the conserved moments (mass and momentum) and the \textit{prescribed diagonal components of the second–order moment tensor} (\( \Pi_{xx} \) and \( \Pi_{yy} \)).
The $H$–function in the quasi-equilibrium states

- It is possible to evaluate explicitly the $H$–function in the quasi-equilibrium IID states, $H_{QE}^{IID} = H(f_{QE}^{IID})$, the result is written as:

$$H_{QE}^{IID} = \rho \ln \rho + \rho \sum_{i=x,y} \sum_{k=-,0,+} w_k a_k(\Pi_{ii}) \ln \left( a_k(\Pi_{ii}) \right), \quad (50)$$

where $w_\pm = w(\pm 1)$, $w_0 = w(0)$, $a_\pm(\Pi_{ii}) = 3 \left( \Pi_{ii} \pm c u_i \right)/c^2$ and $a_0(\Pi_{ii}) = 3 \left( c^2 - \Pi_{ii} \right)/(2 c^2)$.

- Generalizing the result [12], let us derive a new quasi-equilibrium $f_{QE}^{IIT}$ which brings the $H$-function to a minimum among all the population lists with a prescribed trace $T = \Pi_{xx} + \Pi_{yy}$, namely

Definition of Local Quasi-equilibrium ($f_{QE}^{IIT}$)

$f_{QE}^{IIT} \in \{ f_{QE}^{IID} \}$ is the set of generalized Maxwellian states with trace $T$, such that:

$$\left[ \left( \frac{\partial H_{QE}^{IID}}{\partial \Pi_{xx}} \right) - \left( \frac{\partial H_{QE}^{IID}}{\partial \Pi_{yy}} \right) \right]_{(\Pi_{xx} + \Pi_{yy}=T)} = 0.$$
Example (2) of Local Quasi-equilibrium (called IIT)

- The solution to the latter problem exists and yields a cubic equation in terms of the normal stress difference

\[ N = \Pi_{xx}^{IIT} - \Pi_{yy}^{IIT}, \]

\[ N^3 + a N^2 + b N + d = 0, \]

\[ a = -\frac{1}{2} (u_x^2 - u_y^2), \quad b = (2c^2 - T) (T - u^2), \]

\[ d = -\frac{1}{2} (u_x^2 - u_y^2) (2c^2 - T)^2. \]  

Let us define \( p = -a^2/3 + b, \quad q = 2a^3/27 - ab/3 + d \) and \( \Delta = (q/2)^2 + (p/3)^3 \). For \( \Delta \geq 0 \), the Cardano formula implies

\[ \Pi_{xx}^{IIT} = \frac{T}{2} + \frac{1}{2} \left( r - \frac{p}{3 r} - \frac{a}{3} \right), \quad r = \sqrt[3]{-\frac{q}{2} + \sqrt{\Delta}}, \]

while \( \Pi_{yy}^{IIT} = T - \Pi_{xx}^{IIT} \). Thus, substituting (52) into (47), we find

\[ f_{QE}^{IIT} = f_{QE}^{IID} \left( \rho, \mathbf{u}, \Pi_{xx}^{IIT} (\mathbf{u}, T), \Pi_{yy}^{IIT} (\mathbf{u}, T) \right). \]
Unfortunately, we cannot perform the canonical constrained optimization on the D2Q9 lattice by considering the third order moments: hence some pruning must be considered.

Let us modify the moments of quasi-equilibrium IID, namely \( m^{III}_{QE} \), in the following way

\[
m^{III}_{QE} = \rho [1, u_x, u_y, \Pi^{EQ}_{xx}, \Pi^{EQ}_{yy}, u_x u_y, \Pi_{xyy}, \Pi_{xyy}, \Pi^{EQ}_{xx} \Pi^{EQ}_{yy}]^T.
\] (54)

This clearly shows that the quasi–equilibrium moments depend only on the constrained quantities, i.e. the conserved moments (mass and momentum) and the prescribed third order moments (\( \Pi_{xyy} \) and \( \Pi_{xyy} \)).

The pruned quasi-equilibrium is defined as

\[
f^{III}_{QE}(\rho, u, \Pi_{xyy}, \Pi_{xyy}) = M^{-1} \cdot m^{III}_{QE}.
\] (55)

   - Generalization: the quasi-equilibrium chain
Model (1) with blended pressure tensor

- By means of the local equilibrium $f_{EQ}$ and the newly found quasi-equilibrium $f^{IIT}_{QE}$, let us define the blended pressure tensor $E(\Pi^{GE}_{xx}(\beta), \Pi^{GE}_{yy}(\beta))$ as a linear interpolation (function of the free parameter $\beta > 0$) between the points $M(\Pi^{EQ}_{xx}, \Pi^{EQ}_{yy})$ and \(C(\Pi^{IIT}_{xx}, \Pi^{IIT}_{yy})\) on the $\Omega$ plane of parameters, namely

\[
\Pi^E_{ii}(\beta) = \beta \Pi^E_{ii} + (1 - \beta) \Pi^{IIT}_{ii}, \quad \text{for } i = x, y. \tag{56}
\]

- Thus, the generalized equilibrium is defined as

\[
f^{(1)}_{GE}(\beta) = f^{IID}_{QE}(\rho, u, \Pi^{E}_{xx}(\beta), \Pi^{E}_{yy}(\beta)). \tag{57}
\]

and consequently the kinetic model reads

\[
J^{(1)}_Q(f) = \omega \left[ f^{(1)}_{GE}(\beta) - f \right], \tag{58}
\]

where $\omega > 0$ rules the relaxation toward the generalized equilibrium.
Graphical interpretation of the model (1)
Proof of the $H$–theorem for model (1)

$H$–theorem for model $J_Q^{(1)}$

The destruction $\sigma$ due to the relaxation term (58), where $\sigma_Q^{(1)} = \langle \ln \left( f/W \right) J_Q^{(1)}(f) \rangle$, is non-positive and it annihilates at the equilibrium, i.e. $\sigma(f_{EQ}) = 0$, if $0 < \beta \leq \beta^*$ where $\beta^*(f) > 1$.

Proof [part 1 of 2]

Because the $H$-function is convex ($f_2 \ln f_1 \leq f_2 \ln f_2 + f_1 - f_2$) and $f_{QE}^{IID}(\Pi_{xx}, \Pi_{yy})$ minimizes $H$ among all $f$ with the moments $(\Pi_{xx}, \Pi_{yy})$

\[
\sigma_Q^{(1)}/\omega \leq H_{GE}^{(1)}(\beta) - H(f) \leq H_{GE}^{(1)}(\beta) - H_{Q.E}^{IID},
\]

(59)

where $H_{GE}^{(1)}(\beta) = H_{Q.E}^{IID}(\Pi_{xx}^E(\beta), \Pi_{yy}^E(\beta))$. Recalling that tensors in point $O$ and $C$ have the same trace, inequality (59) can be written as

\[
\sigma_Q^{(1)}/\omega \leq H_{GE}^{(1)}(\beta) - H_{GE}^{(1)}(0) + H_{GE}^{(1)}(0) - H_{Q.E}^{IID} \leq H_{GE}^{(1)}(\beta) - H_{GE}^{(1)}(0).
\]
Proof [part 2 of 2]

What remains to estimate is the range of $\beta$ such that $H_{GE}^{(1)}(\beta) \leq H_{GE}^{(1)}(0)$. Clearly, since the equilibrium ($\beta = 1$) is the absolute minimum of $H_{QE}^{IID}$, and because $H_{GE}^{(1)}(\beta)$ is a convex function, $\sigma_Q^{(1)}$ is non-positive if $0 < \beta \leq 1$.

In order to extend the proof to $\beta > 1$, let us consider the entropy estimate [3]:

$$H_{GE}^{(1)}(\beta^*) = H_{GE}^{(1)}(0).$$  \hspace{1cm} (60)

Thanks to the convexity of $H_{GE}^{(1)}(\beta)$, the non-trivial solution $\beta^* > 1$ to this equation is unique when it exists. In the opposite case, we need to take care of the boundary of the positivity domain $\Omega$. In both cases, for $0 < \beta \leq \beta^*$, it holds $H_{GE}^{(1)}(\beta) \leq H_{GE}^{(1)}(0)$ and thus the $H$-function destruction is confirmed, namely $\sigma_Q^{(1)} \leq 0$.  ■
Making things easier...

- Recalling the previous linear mapping for computing the moments, namely

\[
M = [1, v_x, v_y, v_x^2, v_y^2, v_xv_y, v_x^2v_y, v_xv_y^2, v_x^2v_y^2]^T,
\]

and recalling that

\[
m_{QE}^{IID} = \rho [1, u_x, u_y, \Pi_x, \Pi_y, u_xu_y, u_y\Pi_x, u_x\Pi_y, \Pi_x\Pi_y]^T,
\]

it is possible to realize that the moments \(m_{QE}^{IID}\) of this quasi-equilibrium are linear with regards to the prescribed pressure components up to the third order.

- Hence the previous linear interpolation of the pressure tensor components, namely \(\Pi_{ii}^E(\beta) = \beta \Pi_{ii}^{EQ} + (1 - \beta) \Pi_{ii}^{IIP}\) for \(i = x, y\), is equivalent to a linear interpolation of the population lists

\[
f_{GE}^{(2)}(\beta) = \beta f_{EQ}(\rho, u) + (1 - \beta) f_{QE}^{IIP}(\rho, u, \Pi_{xx} + \Pi_{yy}),
\]

up to the third order included.
Let us define the following new collision operator

\[ J_Q^{(2)}(f) = \omega \left[ f_{GE}^{(2)}(\beta) - f \right], \]  

or equivalently, introducing \( \omega = \omega_f \) and \( \beta = \omega_s / \omega_f \),

\[ J_Q^{(2)}(f) = -\omega_f (f - f_{IIT}^{IIT}) - \omega_s (f_{Q IIT}^{IIT} - f_{EQ}). \]

In the previous model, the relaxation to the equilibrium is split in two steps. In the first step, the population list \( f \) relaxes to the quasi-equilibrium \( f_{IIT}^{IIT} \) with the relaxation frequency \( \omega_f \) (fast mode). In the second step, the quasi-equilibrium relaxes to the equilibrium with the second relaxation frequency \( \omega_s \) (slow mode) \([13]\).

The previous model can also be expressed as

\[ J_Q^{(2)}(f) = -\omega_s (f - f_{EQ}) - (\omega_f - \omega_s) (f - f_{Q IIT}^{IIT}). \]
Proof of the $H$–theorem for model (2)

**$H$–theorem for EQE model**

The destruction $\sigma_{Q}^{(2)}$ due to the relaxation term (64), where

$$\sigma_{Q}^{(2)} = \langle \ln \left( \frac{f}{W} \right) J_{Q}^{(2)}(f) \rangle,$$

is non-positive and it annihilates at the equilibrium, i.e. $\sigma_{Q}^{(2)}(f_{EQ}) = 0$, if $\omega_f \geq \omega_s > 0$ (same as $0 < \beta \leq 1$).

**Proof**

Recalling Eq. (65) yields

$$\sigma_{Q}^{(2)} = - \omega_s \langle \ln \left( \frac{f}{f_{EQ}} \right) (f - f_{EQ}) \rangle$$

$$- (\omega_f - \omega_s) \langle \ln \left( \frac{f}{f_{EQ}^{ITT}} \right) (f - f_{EQ}^{ITT}) \rangle,$$

which is non–positive and semi–definite provided that relaxation frequencies satisfy the condition $\omega_f \geq \omega_s$. 
Applying the following variable transformation, namely

\[ f \rightarrow g = f - J_Q/2, \]  

(\( \delta \hat{t} = 1 \) in Boltzmann scaling) to the kinetic model yields

\[ g(\hat{x} + \mathbf{v}, \hat{t} + 1) = (1 - \tilde{\omega}_f)g(\hat{x}, \hat{t}) + \tilde{\omega}_f f_{GE}(\rho, \mathbf{u}, T')(\hat{x}, \hat{t}), \]  

where \( \tilde{\omega}_f = (1/\omega_f + 1/2)^{-1} \), where as usual \( \rho = \langle g \rangle \) and \( \rho u_i = \langle v_i g \rangle \), but, since the trance is not conserved,

\[ T' = (1 - \tilde{\omega}_s/2) T(g) + \tilde{\omega}_s T_{EQ}(g)/2, \]

where \( \tilde{\omega}_s = (1/\omega_s + 1/2)^{-1} \) and

\[ T(g) = \langle (v_x^2 + v_y^2) g \rangle, \quad T_{EQ}(g) = 2/3 \left[ \varphi(u_x/c) + \varphi(u_y/c) - 1 \right]. \]

By means of asymptotic analysis, it is possible to prove that the previous model recovers the Navier–Stokes equations up to the second order w.r.t. space discretization, with a kinematic viscosity \( \nu = (3\omega_f)^{-1} \) and a bulk viscosity \( \xi = (3\omega_s)^{-1} \).
First of all, let us verify the transport coefficients by means of the analytical solution for the Taylor–Green vortex flow.

Effectively this choice allows one to perform calculations with rougher meshes $N \times N$ or (equivalently) higher Mach numbers ($M_{\text{a}} = 0.01$ Re Kn was adopted).

However the previous consideration does not lead automatically to a performance improvement, because the accuracy must be considered as well.

The key result is that the EQE model, with a rougher mesh $170^2 \sim 250^2/2$ than that used by the BGK model, can achieve the same accuracy ($2.76\% \sim 2.72\%$).

This gives to the EQE model an effective computational speed-up of 2.84 times over the BGK model (!!).

Lid driven cavity at $\text{Re} = 5000$: EQE vs. BGK

$\text{Re}=5000$, $\text{Time}=100$, $v=0.0002$, (EQE $\xi=0.0020$)
Why does model (2) work better than BGK?

- Intermediate quasi-equilibrium $f^{IIT}_{QE}$ decouples the relaxation of the (spurious) acoustic modes from the shear modes.
- Consequently the generalized local equilibrium (GE) allows one to tune the bulk viscosity to larger values (as compared to the BGK), which was found to help suppressing spurious acoustic modes.
- Tunable bulk viscosity is a free parameter to dump the compressibility error, when searching for the incompressible limit of the Navier-Stokes equations.
- Unfortunately there are many sources of instability and the spurious acoustic modes represent only one trigger (see the lecture by Professor Ohwada later today about ACM where the same sources of instability appear and where different techniques are designed for the fortification of the numerical method).
Particularly in three dimensions, another mode (so-called checkerboard mode) is known to contaminate the BGK pressure field, through a coupling of the pressure relaxation to the energy flux (or, in other words, the coupling between the second-order and the third-order moments) (Dellar [20]).

Of course, model (2), as well as all models based on quasi-equilibria which depend only on moments up to the second order, cannot help to fix this instability mode.

On the other hand, the so-called one-belt lattices have not enough degrees of freedom to deal with complete quasi-equilibria involving all third order moments: hence, in the example (3), we discussed a pruned quasi-equilibrium involving non-unidirectional third order moments, namely

\[ f_{III\,QE}^{III} = M^{-1} \cdot m_{III\,QE}^{III} \]

where

\[ m_{III\,QE}^{III} = \rho \left[ 1, u_x, u_y, \Pi_{xx}^{EQ}, \Pi_{yy}^{EQ}, u_x u_y, \Pi_{xy}, \Pi_{yy}, \Pi_{xx}\Pi_{yy} \right]^T. \]

(68)
Model (3) with pruned quasi-equilibrium

- Consequently it is possible to define a new generalized local equilibrium, namely

\[
    f_{GE}^{(3)}(\omega_s/\omega_f) = \omega_s/\omega_f \ f_{EQ}(\rho, u) + (1 - \omega_s/\omega_f) \ f_{III}^{QE}(\rho, u, \Pi_{xxy}, \Pi_{xyy}),
\]

(69)

and a kinetic model, namely

\[
    J_Q^{(3)}(f) = \omega_f \ [f_{GE}^{(3)}(\omega_s/\omega_f) - f].
\]

(70)

- The previous model allows one to decouple the relaxation of the third-order moments from the relaxation of the pressure tensor.

- It is interesting to note that relaxing differently the third-order moments is equivalent to change the equilibrium definitions of the fourth-order moments (Dellar [20]), which are known to drive the checkerboard instability (since both pressure and fourth-order moments belong to the so-called even/backbone moments).
The computational domain is discretized by a uniform collocated grid with $N^3$ points with $N = 60$. The Reynolds number is $Re = 2000$ and consequently the relaxation parameter controlling the kinematic viscosity is equal to $\omega_s \approx 1.9646$ [8].
Checkerboard mode degrades BGK pressure field

            Fqe(:) = (tau1/tau2)*Feq(:)+(1.0-tau1/tau2)*Fqe(:);
            Fp(i,j,k,:) = F(i,j,k,:)+(Fqe(:)-F(i,j,k,:))/(tau1);
        enddo
    enddo
endo
Let us define the following generalized collision operator

$$J_{QN}(f) = \sum_{n=1}^{N} \omega_n \left[ f_{QE} n - f_{QE} (n-1) \right]. \quad (71)$$

where $f_{QE} 0 = f$ and $f_{QE} N = f_{EQ}$.

Alternatively, $J_{NQ}(f) = \omega_1 (f_{GE} - f)$, where

$$f_{GE} = \sum_{n=2}^{N} \omega_n / \omega_1 \left[ f_{QE} n - f_{QE} (n-1) \right] + f_{QE} 1. \quad (72)$$

Finally, another equivalent formulation is

$$J_{QN}(f) = \sum_{n=1}^{N} (\omega_n - \omega_{n+1}) \left[ f_{QE} n - f \right], \quad (73)$$

where $\omega_{N+1} = 0$. Similarly to the proof of the H–theorem for model (2), the previous expression allows to prove that $\omega_n \geq \omega_{n+1}$. 
Because of the conserved quantities and the physical symmetries, $N < Q$ where $Q$ is the number of lattice velocities in the considered lattice. However $N$ is still the maximum number of parameters (i.e. transport coefficients) for controlling the dynamics.

There are clearly some analogies with the multiple-relaxation-time (MRT) collisional operator [6, 7, 8].

However there are also important differences (e.g. hierarchical ordered sequence of relaxation frequencies, maximum number of tunable parameters equal to the maximum number of moments which can be constrained...).

It is worth the effort to systematically explore the connection between a quasi-equilibrium chain and a corresponding MRT model (if any).
Concerning the advection process, we discussed some relevant scalings for analyzing the numerical results by asymptotic analysis. This allows to link the LBM to other similar methods, e.g. the Artificial Compressibility Method (ACM).

The quasi-equilibrium (QE) concept and consequently the generalized equilibrium (GE) were discussed, also by some specific examples on the simplest lattices. This provides a general framework for proceeding beyond BGK relaxation in a systematic way (at least coherent with transport theory).

Three models based on these concepts were analyzed in terms of both (a) practical numerical implementation and (b) obtained numerical results. The corresponding FORTRAN codes are available for interested students.
Thank you for your attention !!
